

# Meet the Agentic Development Team

Coding agents are highly trained virtual interns that are eager to please, able to whip out code with amazing speed, and are prone to forgetting everything. We have a (theoretically) unlimited number of them at our disposal.

This session is about how to move from using agents like tools to onboarding them onto the development team. We will explore giving your agents defined roles, persistent instructions, isolated environments, and clear handoffs.

We will build an agentic development workflow where multiple coding agents collaborate on the same project. One agent will implement features, another will independently review pull requests, and another will coordinate everything.

Our team will communicate through Slack, while Git, Skills, and specifications provide the shared knowledge that survives individual conversations.

Along the way, we'll explore practical techniques for building a more reliable agentic development workflow, including:

- onboarding agents with Skills
- using specifications and acceptance criteria instead of vague prompts
- enforcing architectural boundaries with automated tests
- using mutation testing to verify that tests actually detect defects
- assigning implementation and review to different models
- giving agents safe environments for “YOLO mode”
- building feedback loops that let agents discover and correct their mistakes

As developers, the goal is to move from supervising every line of code to designing the environment, rules, roles, and feedback systems that enable our agentic development team to work effectively.

You'll leave with concrete patterns you can apply to Claude Code, Codex, and other coding agents to make agentic development more repeatable, testable, and trustworthy.

## Jeremy Davis

Jeremy is a Field Architect at Docker. He helps Docker's customers to design and deliver solutions, works with Docker engineers to create great products, and occasionally speaks at conferences.

Before joining Docker he did essentially the same thing at Red Hat, and wrote a lot of code in C, C#, Groovy, Java, JavaScript, Objective-C, Perl, PHP, Python, Ruby, Visual Basic; mostly Java.

He recently acquired a Marshall amp after relying on Fenders for years.
